Where each merge puts its energy, four bases
share of squared norm in the bottom quarter of $\hat{H}$'s spectrum
norm of the merged update / norm of the mean task update
independent arm (open): every merge at 0.2 to 0.3, close to what a generic direction gives
unregularised solvers, shared: 35 to 57 times the mean update, about 3/4 of it in the bottom quarter
shared arm (filled): averaging, sparsifying and ridged solvers put almost nothing in the ill-conditioned quarter
averaging and sparsifying (TA, TIES, DARE, TVQ)
solvers built from the adapters, no ridge
the same solvers with a ridge
exact interpolator $\bar{\tau}_H$
